

Lab Assignment-13

Name: D.BHARATH KUMAR

Hallticket:2303A51097

Batch-02

Task Description #1 (Refactoring – Removing Code Duplication)

- Task: Use AI to refactor a given Python script that contains multiple repeated code blocks.

- Instructions:

- o Prompt AI to identify duplicate logic and replace it with functions or classes.

- o Ensure the refactored code maintains the same output.

- o Add docstrings to all functions.

- Sample Legacy Code:

```
# Legacy script with repeated logic  
print("Area of Rectangle:", 5 * 10)  
print("Perimeter of Rectangle:", 2 * (5 + 10))  
print("Area of Rectangle:", 7 * 12)  
print("Perimeter of Rectangle:", 2 * (7 + 12))  
print("Area of Rectangle:", 10 * 15)  
print("Perimeter of Rectangle:", 2 * (10 + 15))
```

- Expected Output:

- o Refactored code with a reusable function and no duplication.

- o Well documented code

screenshots:

assg_13.py > validate_dimensions

```
1 def validate_dimensions(length, width):
2     """
3     Validate that dimensions are positive numbers.
4
5     Args:
6         length: The length of the rectangle
7         width: The width of the rectangle
8
9     Returns:
10        bool: True if valid, raises ValueError otherwise
11    """
12    if not isinstance(length, (int, float)) or not isinstance(width, (int, float)):
13        raise ValueError("Dimensions must be numbers")
14    if length <= 0 or width <= 0:
15        raise ValueError("Dimensions must be positive")
16    return True
17
18
19 def calculate_area(length, width):
20     """
21     Calculate the area of a rectangle.
22
23     Args:
24         length: The length of the rectangle
25         width: The width of the rectangle
26
27     Returns:
28         float: The area of the rectangle
29    """
30    validate_dimensions(length, width)
31    return length * width
32
33
34 def calculate_perimeter(length, width):
35     """
36     Calculate the perimeter of a rectangle.
37
38     Args:
39         length: The length of the rectangle
40         width: The width of the rectangle
41
42     Returns:
43         float: The perimeter of the rectangle
44    """
45    validate_dimensions(length, width)
46    return 2 * (length + width)
47
48
49 def print_rectangle_info(length, width):
50     """
51     Print area and perimeter of a rectangle.
52

Perimeter of Rectangle: 50
PS C:\Users\BHARATH\OneDrive\Pictures\Desktop\AIAC> |
```

Task Description #2 (Refactoring – Extracting Reusable Functions)

- Task: Use AI to refactor a legacy script where multiple calculations are embedded directly inside the main code block.

- Instructions:

- o Identify repeated or related logic and extract it into reusable functions.

- o Ensure the refactored code is modular, easy to read, and documented with docstrings.

- Sample Legacy Code:

```
# Legacy script with inline repeated logic
```

```
price = 250
```

```
tax = price * 0.18
```

```
total = price + tax
```

```
print("Total Price:", total)
```

```
price = 500
```

```
tax = price * 0.18
```

```
total = price + tax
```

```
print("Total Price:", total)
```

- Expected Output:

- o Code with a function `calculate_total(price)` that can be reused for multiple price inputs.

- o Well documented code

screenshots:

```

38 #refactor the code identify the repeated or related logics from the code extract into the reusable function and use that function in the main code to avoid code repetition and make the code more modular and maintainable
39
40 def calculate_total_price(price):
41     """
42     Calculate the total price including tax.
43     This function takes a price and calculates the total cost by adding an 18% tax
44     to the original price.
45     Args:
46         price (int or float): The base price before tax. Must be a non-negative number.
47     Returns:
48         Float: The total price including 18% tax.
49     Raises:
50         TypeError: If price is not a number (int or float).
51         ValueError: If price is negative.
52     Example:
53         >>> calculate_total_price(100)
54         118.0
55         >>> calculate_total_price(50.5)
56         59.59
57     """
58     if not isinstance(price, (int, float)):

Total Price: 590.0
Total Price: 590.0
PS C:\Users\BHARATH\OneDrive\Pictures\Desktop\AIAC>

```

Task Description #3: Refactoring Using Classes and Methods (Eliminating Redundant Conditional Logic)

Refactor a Python script that contains repeated if–elif–else grading logic by implementing a structured, object-oriented solution using a class and a method.

Problem Statement

The given script contains duplicated conditional statements used to assign grades based on student marks. This redundancy violates clean code principles and reduces maintainability.

You are required to refactor the script using a class-based design to improve modularity, reusability, and readability while preserving the original grading logic.

Mandatory Implementation Requirements

1. Class Name: GradeCalculator
2. Method Name: calculate_grade(self, marks)
3. The method must:

- o Accept marks as a parameter.
- o Return the corresponding grade as a string.
- o The grading logic must strictly follow the conditions below:
 - Marks ≥ 90 and $\leq 100 \rightarrow$ "Grade A"
 - Marks $\geq 80 \rightarrow$ "Grade B"
 - Marks $\geq 70 \rightarrow$ "Grade C"
 - Marks $\geq 40 \rightarrow$ "Grade D"
 - Marks $\geq 0 \rightarrow$ "Fail"

Note: Assume marks are within the valid range of 0 to 100.

4. Include proper docstrings for:

- o The class
- o The method (with parameter and return descriptions)

5. The method must be reusable and called multiple times without rewriting conditional logic.

• Given code:

```
marks = 85
if marks >= 90:
    print("Grade A")
elif marks >= 75:
    print("Grade B")
else:
    print("Grade C")

marks = 72
if marks >= 90:
    print("Grade A")
elif marks >= 75:
    print("Grade B")
else:
    print("Grade C")
```

Expected Output:

- Define a class named GradeCalculator.

- Implement a method `calculate_grade(self, marks)` inside the class.
- Create an object of the class.
- Call the method for different student marks.
- Print the returned grade values.

Screenshots:

```

68 #refactor the given code that contains if elif else grading statements by implementing a structured object oriented solution using class and a method
69 ## Marks ≥ 80 → "Grade B"
70 ## Marks ≥ 70 → "Grade C"
71 ## Marks ≥ 40 → "Grade D"
72 ## Marks ≥ 0 → "Fail"
73 #include proper docstring and error handling for invalid input and class and method (with parameters) to calculate the grade based on the marks provide
74 class GradeCalculator:
75     def __init__(self, marks):
76         self.marks = marks
77
78     def calculate_grade(self):
79         if not isinstance(self.marks, (int, float)):
80             raise TypeError("Marks must be a number.")
81         if self.marks < 0 or self.marks > 100:
82             raise ValueError("Marks must be between 0 and 100.")
83
84         if self.marks >= 90:
85             return "Grade A"
86         elif self.marks >= 80:
87             return "Grade B"
88         elif self.marks >= 70:
89             return "Grade C"
90         elif self.marks >= 40:
91             return "Grade D"
92         else:
93             return "Fail"
94
95 marks = 85
96 if marks >= 90:
97     print("Grade A")
98 elif marks >= 75:
99     print("Grade B")

Task Description #4 (Refactoring – Converting Procedural Code to Functions)

- Task: Use AI to refactor procedural input–processing logic into functions.

Instructions:

- o Identify input, processing, and output sections.

- o Convert each into a separate function.
- o Improve code readability without changing behavior.

- Sample Legacy Code:

```
num = int(input("Enter number: "))

square = num * num

print("Square:", square)
```

- Expected Output:

- o Modular code using functions like get_input(), calculate_square(), and display_result().

Screenshots:

```
108 #identify input ,processing and output sections and convert them into a separate function for each section like and add docstrings to each function
109 def get_input():
110     """Function to get input from the user."""
111     try:
112         num = int(input("Enter number: "))
113         return num
114     except ValueError:
115         print("Invalid input. Please enter a valid integer.")
116         return None
117 def process_input(num):
118     """Function to process the input and calculate the square."""
119     if num is not None:
120         return num ** 2
121     return None
122 def display_output(result):
123     """Function to display the output."""
124     if result is not None:
125         print(f"The square of the number is: {result}")
126     else:
127         print("No result to display.")
```

```
108 #identify input ,processing and output sections and convert them into a separate function for each section like and add docstrings to each function
109 def get_input():
110     """Function to get input from the user."""
111     try:
112         num = int(input("Enter number: "))
113         return num
114     except ValueError:
115         print("Invalid input. Please enter a valid integer.")
116         return None
117 def process_input(num):
118     """Function to process the input and calculate the square."""
119     if num is not None:
120         return num ** 2
121     return None
122 def display_output(result):

129     """Main function to orchestrate the input, processing, and output."""
130     num = get_input()
131     result = process_input(num)
132     display_output(result)
133 if __name__ == "__main__":
134     main()
```

Output:

```
PS C:\Users\BHARATH\OneDrive\Pictures\Desktop\AIAC> & C:\Users\BHARATH\AppData\Local\Programs\Python\Python313\python.exe "c:/Users/BHARATH/OneDrive/Pictures/Desktop/AIAC/assg_13 (1).py"
Enter number: 100
The square of the number is: 10000
PS C:\Users\BHARATH\OneDrive\Pictures\Desktop\AIAC>
```

Task 5 (Refactoring Procedural Code into OOP Design)

- Task: Use AI to refactor procedural code into a class-based design.

Focus Areas:

- o Object-Oriented principles
- o Encapsulation

Legacy Code:

```
salary = 50000

tax = salary * 0.2

net = salary - tax

print(net)
```

Expected Outcome:

A class like EmployeeSalaryCalculator with methods and attributes.

Screenshots:

```
132 #refactor the code into the procedural code into a class -based design main focus on the object ooriented line encapsulation
133 |
134 class SalaryCalculator:
135     """Class to calculate salary and tax with encapsulation."""
136
137     def __init__(self, salary):
138         """Initialize SalaryCalculator with salary amount.
139
140         Args:
141             salary: The base salary amount
142         """
143         self._salary = salary
144
145     def _validate_salary(self):
146         """Validate that salary is a positive number.
147
148         Raises:
149             ValueError: If salary is not positive or not a number
150         """
151         if not isinstance(self._salary, (int, float)):
152             raise ValueError("Salary must be a number.")
153         if self._salary < 0:
154             raise ValueError("Salary must be non-negative.")
155
156     def calculate_tax(self):
157         """Calculate tax on the salary.

Tax (20%): 10000.0
Net Salary: 40000.0
PS C:\Users\BHARATH\OneDrive\Pictures\Desktop\AIAC>
```

Task 6 (Optimizing Search Logic)

- Task: Refactor inefficient linear searches using appropriate data structures.

- Focus Areas:

- o Time complexity
- o Data structure choice

Legacy Code:

```
users = ["admin", "guest", "editor", "viewer"]

name = input("Enter username: ")

found = False

for u in users:

    if u == name:

        found = True

    print("Access Granted" if found else "Access Denied")
```

Expected Outcome:

- o Use of sets or dictionaries with complexity justification

screenshots:

```
172 # refactor the code to inefficient liner searches using apporiate data and focus on the time complexity and data structures edit tghe code to the b
173
174 # Using a set for O(1) average-case lookup instead of O(n) list search
175 users = {"admin", "guest", "editor", "viewer"}
176 name = input("Enter username: ")
177 found = name in users
178 print("Access Granted" if found else "Access Denied")
179
```

Output:

```
PS C:\Users\BHARATH\OneDrive\Pictures\Desktop\AIAC> & C:\Users\BHARATH\AppData\Local\Programs\Python\Python313\python.exe "c:/Users/BHARATH/OneDrive/Pictures/Desktop/AIAC/assg_13 (1).py"
Enter username: admin
Access Granted
PS C:\Users\BHARATH\OneDrive\Pictures\Desktop\AIAC>
```

Task 7 – Refactoring the Library Management System

Problem Statement

You are provided with a poorly structured Library Management script that:

- Contains repeated conditional logic
- Does not use reusable functions
- Lacks documentation
- Uses print-based procedural execution
- Does not follow modular programming principles

Your task is to refactor the code into a proper format

1. Create a module library.py with functions:

- o add_book(title, author, isbn)
- o remove_book(isbn)
- o search_book(isbn)

2. Insert triple quotes under each function and let Copilot complete the docstrings.

3. Generate documentation in the terminal.

4. Export the documentation in HTML format.

5. Open the file in a browser.

Given Code

```
# Library Management System (Unstructured Version)

# This code needs refactoring into a proper module with documentation.

library_db = {}

# Adding first book

title = "Python Basics"

author = "John Doe"

isbn = "101"

if isbn not in library_db:

    library_db[isbn] = {"title": title, "author": author}

    print("Book added successfully.")

else:

    print("Book already exists.")

# Adding second book (duplicate logic)

title = "AI Fundamentals"

author = "Jane Smith"
```

```
isbn = "102"

if isbn not in library_db:

    library_db[isbn] = {"title": title, "author": author}

    print("Book added successfully.")

else:

    print("Book already exists.")

library [c:\users\bharath\onedrive\pictures\desktop\aiac\library.py](#)

Functions

add_book(title, author, isbn)

This function creates a new book entry in the library database using the provided bibliographic information. It validates that all required parameters are supplied and checks for duplicate entries to maintain data integrity.

title (str): The title of the book. Must be a non-empty string representing the full name of the publication.

author (str): The author of the book. Must be a non-empty string containing the name(s) of the book's author(s).

isbn (str): The International Standard Book Number of the book. Must be a non-empty string that serves as a unique identifier for the book in the database. This acts as the primary key to prevent duplicate entries.

book: True if the book was successfully added to the database, indicating a new entry was created. False if a book with the same ISBN already exists in the database, indicating the operation was rejected to prevent duplicate entries.

ValueError: If any of the required parameters (title, author, or isbn) is empty, None, or evaluates to a falsy value. This ensures data quality by preventing incomplete book records from being added to the database.

Examples:

```
>>> add_book("The Great Gatsby", "F. Scott Fitzgerald", "978-0-7432-7356-5")
```

```
Book added successfully.
```

```
True
```

```
>>> add_book("The Great Gatsby", "F. Scott Fitzgerald", "978-0-7432-7356-5")
```

```
Book already exists.
```

```
False
```

```
>>> add_book("", "F. Scott Fitzgerald", "978-0-7432-7356-5")
```

```
ValueError: Title, author, and ISBN cannot be empty.
```

remove_book(isbn)

Remove a book from the library database by ISBN.

Args:

isbn (str): The ISBN of the book to remove.

Task 8– Fibonacci Generator

Write a program to generate Fibonacci series up to n.

The initial code has:

- Global variables.
- Inefficient loop.
- No functions or modularity.

Task for Students:

- Refactor into a clean reusable function (generate_fibonacci).
- Add docstrings and test cases.
- Compare AI-refactored vs original.

Bad Code Version:

```
# fibonacci bad version
```

```
n=int(input("Enter limit: "))
```

```
a=0
```

```
b=1
```

```

print(a)

print(b)

for i in range(2,n):

c=a+b

print(c)

a=b

b=c

```

screenshots:

```

226 # refactor the code as per the • Refactor into a clean reusable function (generate_fibonacci)., Add docstrings and test cases., Compare AI-refactored
227

Task 9 – Twin Primes Checker

Twin primes are pairs of primes that differ by 2 (e.g., 11 and 13, 17 and 19).

The initial code has:

- Inefficient prime checking.
- No functions.
- Hardcoded inputs.

Task for Students:

- Refactor into `is_prime(n)` and `is_twin_prime(p1, p2)`.
- Add docstrings and optimize.
- Generate a list of twin primes in a given range using AI.

Bad Code Version:

```
# twin primes bad version

a=11

b=13

fa=0

for i in range(2,a):

    if a%i==0:

        fa=1

fb=0

for i in range(2,b):

    if b%i==0:

        fb=1

if fa==0 and fb==0 and abs(a-b)==2:

    print("Twin Primes")

else:

    print("Not Twin Primes")
```

screenshots:

```

250 # refactor the code as per the instructions Refactor into is_prime(n) and is_twin_prime(p1, p2).. Add docstrings and optimize.,Generate a list of twin primes in a given range using AI.
251 def is_prime(n):
252     """
253     Check if a number is prime.
254

Task 10 – Refactoring the Chinese Zodiac Program

Objective

Refactor the given poorly structured Python script into a clean, modular, and reusable implementation.

The current program reads a year from the user and prints the corresponding Chinese Zodiac sign. However, the implementation contains repetitive conditional logic, lacks modular design, and does not follow clean coding principles.

Your task is to refactor the code to improve readability, maintainability, and structure.

Chinese Zodiac Cycle (Repeats Every 12 Years)

1. Rat
2. Ox
3. Tiger
4. Rabbit
5. Dragon
6. Snake
7. Horse
8. Goat (Sheep)
9. Monkey
10. Rooster
11. Dog
12. Pig

Chinese Zodiac Program (Unstructured Version)

This code needs refactoring.

```
year = int(input("Enter a year: "))  
  
if year % 12 == 0:  
    print("Monkey")  
  
elif year % 12 == 1:  
    print("Rooster")  
  
elif year % 12 == 2:  
    print("Dog")  
  
elif year % 12 == 3:  
    print("Pig")  
  
elif year % 12 == 4:  
    print("Rat")  
  
elif year % 12 == 5:  
    print("Ox")  
  
elif year % 12 == 6:  
    print("Tiger")  
  
elif year % 12 == 7:
```

```

print("Rabbit")

elif year % 12 == 8:

print("Dragon")

elif year % 12 == 9:

print("Snake")

elif year % 12 == 10:

print("Horse")

elif year % 12 == 11:

print("Goat")

```

You must:

1. Create a reusable function: `get_zodiac(year)`
2. Replace the if-elif chain with a cleaner structure (e.g., list or dictionary).
3. Add proper docstrings.
4. Separate input handling from logic.
5. Improve readability and maintainability.
6. Ensure output remains correct.

Screenshots:

```

286 #refactor the code as per the instructions 1. Create a reusable function: get_zodiac(year)2. Replace the if-elif chain with a cleaner struc
287
288 def get_zodiac(year):
289     """Return the zodiac sign for a given year."""
290     zodiacs = [
291         "Monkey", "Rooster", "Dog", "Pig", "Rat", "Ox",
292         "Tiger", "Rabbit", "Dragon", "Snake", "Horse", "Goat"
293     ]
294     return zodiacs[year % 12]
295
296 def main():
297     try:
298         year = int(input("Enter a year: "))
299         zodiac_sign = get_zodiac(year)
300         print(f"The zodiac sign for the year {year} is: {zodiac_sign}")
301     except ValueError:
302         print("Invalid input. Please enter a valid integer for the year.")
303
304 if __name__ == "__main__":
305     main()

```

Output:

The zodiac sign for the year 2024 is: Dragon
PS C:\Users\BHARATH\OneDrive\Pictures\Desktop\AIAC>

```

Task 11 – Refactoring the Harshad (Niven) Number Checker

Refactor the given poorly structured Python script into a clean, modular, and reusable implementation.

A Harshad (Niven) number is a number that is divisible by the sum of its digits.

For example:

- $18 \rightarrow 1 + 8 = 9 \rightarrow 18 \div 9 = 2$ (Harshad Number)
- $19 \rightarrow 1 + 9 = 10 \rightarrow 19 \div 10 \neq \text{integer}$ (Not Harshad)

Problem Statement

The current implementation:

- Mixes logic and input handling
- Uses redundant variables
- Does not use reusable functions properly
- Returns print statements instead of boolean values
- Lacks documentation

You must refactor the code to follow clean coding principles.

Harshad Number Checker (Unstructured Version)

```
num = int(input("Enter a number: "))

temp = num

sum_digits = 0

while temp > 0:

    digit = temp % 10

    sum_digits = sum_digits + digit

    temp = temp // 10

if sum_digits != 0:

    if num % sum_digits == 0:

        print("True")

    else:

        print("False")

    else:
```

```
print("False")
```

You must:

1. Create a reusable function: `is_harshad(number)`
2. The function must:
 - o Accept an integer parameter.
 - o Return True if the number is divisible by the sum of its digits.
 - o Return False otherwise.
3. Separate user input from core logic.
4. Add proper docstrings.
5. Improve readability and maintainability.

Screenshots:

```
303 # refactor the code as per the instructions 1. Create a reusable function: is_harshad(number), 2. The function must: Accept an integer parameter., Return True if the number is div
304 def is_harshad(number):
305     """
306     Check if a number is a Harshad number.
307
308     A Harshad number is an integer that is divisible by the sum of its digits.
309
310     Args:
311         number (int): The number to check.
312     Returns:
313         bool: True if the number is a Harshad number, False otherwise.
314     """
315     if number <= 0:
316         return False
317
318     temp = number
319     sum_digits = 0
320
321     while temp > 0:
322         digit = temp % 10
323         sum_digits += digit
324         temp //= 10
325
326     return sum_digits != 0 and number % sum_digits == 0
327 def main():
328     try:
329         num = int(input("Enter a number: "))
330         if is_harshad(num):
331             print("True")
332         else:
333             print("False")
334     except ValueError:
335         print("Invalid input. Please enter a valid integer.")
336 if __name__ == "__main__":
337     main()
338
```

Output:

True
PS C:\Users\BHARATH\OneDrive\Pictures\Desktop\AIAC> |
```

Task 12 – Refactoring the Factorial Trailing Zeros Program

Refactor the given poorly structured Python script into a clean, modular, and efficient implementation.

The program calculates the number of trailing zeros in $n!$ (factorial of n).

Problem Statement

The current implementation:

- Calculates the full factorial (inefficient for large n)
- Mixes input handling with business logic
- Uses print statements instead of return values
- Lacks modular structure and documentation

You must refactor the code to improve efficiency, readability, and maintainability.

```
# Factorial Trailing Zeros (Unstructured Version)

n = int(input("Enter a number: "))

fact = 1

i = 1

while i <= n:

    fact = fact * i

    i = i + 1

count = 0

while fact % 10 == 0:

    count = count + 1

    fact = fact // 10

print("Trailing zeros:", count)
```

You must:

1. Create a reusable function: `count_trailing_zeros(n)`
2. The function must:
 - o Accept a non-negative integer n .
 - o Return the number of trailing zeros in $n!$.
3. Do NOT compute the full factorial.
4. Use an optimized mathematical approach (count multiples of 5).
5. Add proper docstrings.
6. Separate user interaction from core logic.
7. Handle edge cases (e.g., negative numbers, zero).

Screenshots:

```
330 #REFACTOR THE CODE AS PER THE INSTRUCTIONS 1. Create a reusable function: count_trailing_zeros(n)2. The function must: o Accept a non-negative integer n.o Return the number of trailing zeros in n!
331 def count_trailing_zeros(n):
332
333     if n < 0:
334         raise ValueError("Input must be a non-negative integer.")
335
336     count = 0
337     power_of_5 = 5
338
339     while n >= power_of_5:
340         count += n // power_of_5
341         power_of_5 *= 5
342
343     return count
344
345 def main():
346     try:
347         n = int(input("Enter a non-negative integer: "))
348         zeros = count_trailing_zeros(n)
349         print(f"The number of trailing zeros in {n}! is: {zeros}")
350     except ValueError as e:
351         print(f"Error: {e}")
352
353 if __name__ == "__main__":
354     main()
```

Output:

```
PS C:\Users\BHARATH\OneDrive\Pictures\Desktop\AIAC> & C:\Users\BHARATH\AppData\Local\Programs\Python\Python313\python.exe c:/Users/BHARATH/OneDrive/Pictures/Desktop/AIAC/assg_13.py
Enter a non-negative integer: 15
The number of trailing zeros in 15! is: 3
PS C:\Users\BHARATH\OneDrive\Pictures\Desktop\AIAC>
```

Task 13 (Collatz Sequence Generator – Test Case Design)

- Function: Generate Collatz sequence until reaching 1.
- Test Cases to Design:
 - Normal: $6 \rightarrow [6, 3, 10, 5, 16, 8, 4, 2, 1]$
 - Edge: $1 \rightarrow [1]$
 - Negative: -5
 - Large: 27 (well-known long sequence)
- Requirement: Validate correctness with pytest.

Explanation:

We need to write a function that:

- Takes an integer n as input.
- Generates the Collatz sequence (also called the $3n+1$ sequence).
- The rules are:
 - o If n is even \rightarrow next = $n / 2$.
 - o If n is odd \rightarrow next = $3n + 1$.
- Repeat until we reach 1.
- Return the full sequence as a list.

Example

Input: 6

Steps:

- 6 (even $\rightarrow 6/2 = 3$)
- 3 (odd $\rightarrow 3*3+1 = 10$)
- 10 (even $\rightarrow 10/2 = 5$)
- 5 (odd $\rightarrow 3*5+1 = 16$)
- 16 (even $\rightarrow 16/2 = 8$)
- 8 (even $\rightarrow 8/2 = 4$)
- 4 (even $\rightarrow 4/2 = 2$)
- 2 (even $\rightarrow 2/2 = 1$)

Output:

[6, 3, 10, 5, 16, 8, 4, 2, 1]

Screenshots:

```

354
355 """
356 We need to write a function that:
357 • Takes an integer n as input.
358 • Generates the Collatz sequence (also called the 3n+1 sequence).
359 • The rules are:
360   o If n is even → next = n / 2.
361   o If n is odd → next = 3n + 1.
362 • Repeat until we reach 1.
363 • Return the full sequence as a list.
364
365 """
